W4111 – Introduction to Databases
Section 003, V03, Fall 2024
Lecture 3: ER(2), Relational(2), SQL(2)

# Today's Contents

## Contents

• Introduction and course updates.

• ER Modeling (2).

- Relational model and algebra (2).
- SQL (2).

Homework and projects.

Introduction and course updates

## Course Updates

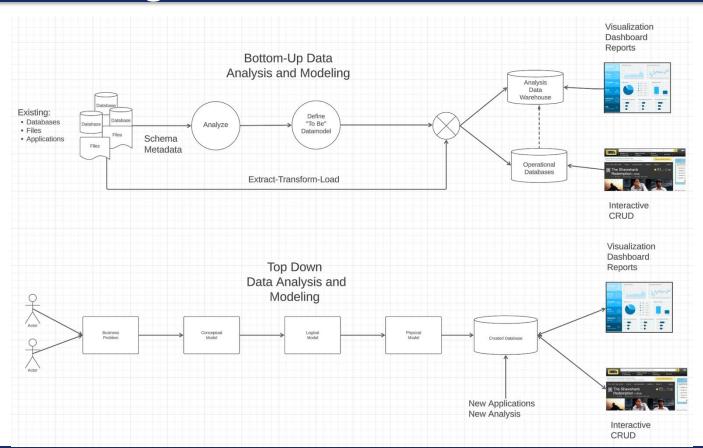

- Homework assignments:
  - In general, a homework has two parts, e.g. HW1a and HW1b.
    - "a" is written questions, and you have one week to complete.
    - "b" is practical "tasks," that also work towards a simple project at the end. You typically have two weeks to complete.
  - Tentative schedule:
    - HW1: 21-SEP
    - HW2: 5-OCT
    - HW3: 19-OCT
    - HW4: 2-NOV
    - HW5: 16-NOV
- The midterm is 18-OCT. We will come up with accommodations for students that have "legitimate," constraints, e.g. religious commitments.

# **ER Modeling**

# Concepts

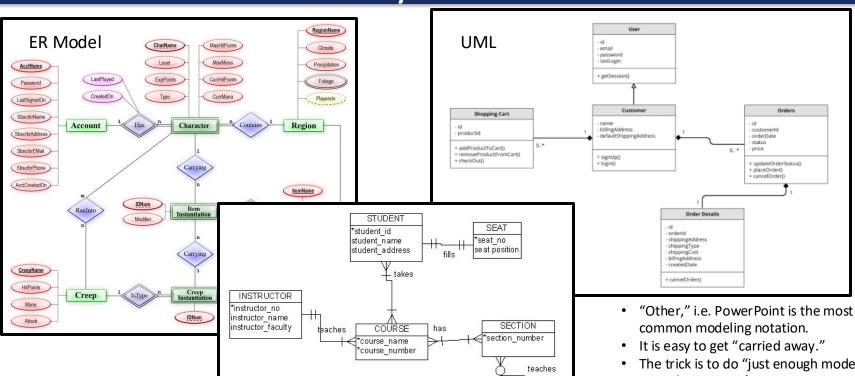

# Modeling

Most of the time there is a mix → Meet-in-the-Middle

## Visual Notation – Many Notations

PROFESSOR

professor faculty

professor id professor name

- The trick is to do "just enough modeling."
- I mostly use Crow's Foot
  - It is "just enough"
  - But lacks some capabilities.
- The book uses ER notation.

Crow's Foot

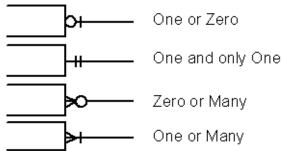

# Notation has Precise Meaning (Crow's Foot)

- Attribute annotations:
  - PK = Primary Key
  - FK = Foreign Key

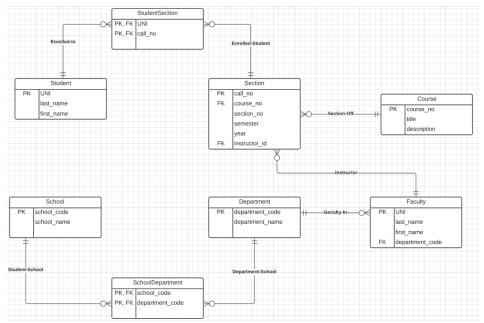

- We will spend a lot of time discussing keys.
- We will start in a couple of slides.

Line annotations:

#### Summary of Crow's Foot Notation

We will learn over time and there are good tutorials (https://www.lucidchart.com/pages/er-diagrams) to help study and refresh.

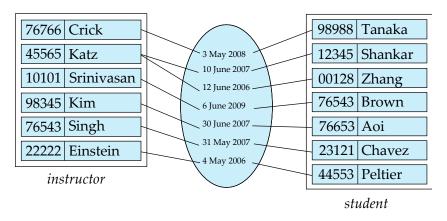

# Entity-Relational Modeling Design Patterns

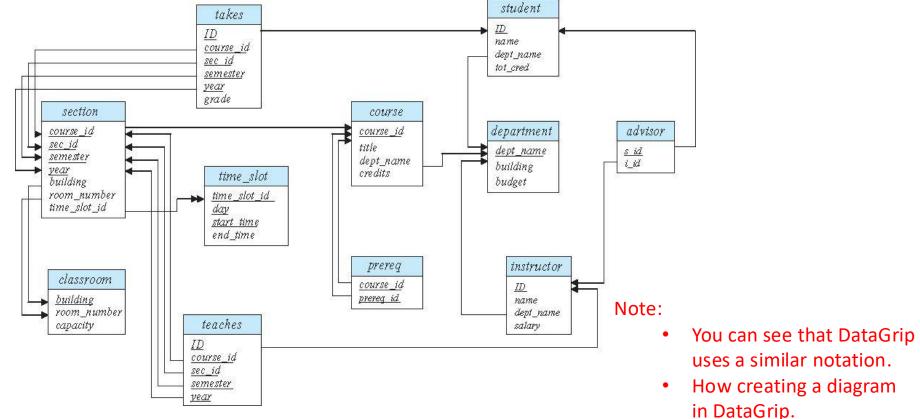

#### **Relationship Sets (Cont.)**

- An attribute can also be associated with a relationship set.
- For instance, the advisor relationship set between entity sets instructor and student may have the attribute date which tracks when the student started being associated with the advisor

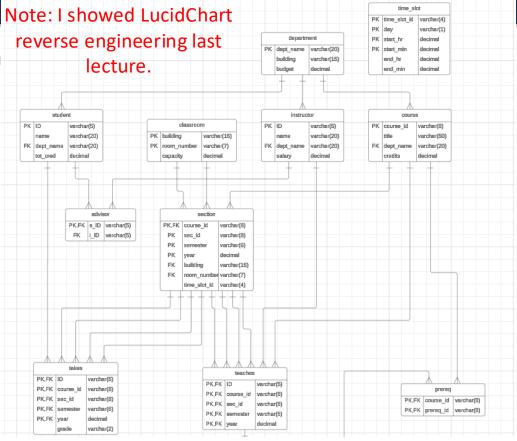

#### **Schema Diagram for University Database**

## Some Observations

- Reverse engineering seems to have ma
- But, notice that sometimes:
  - Relationship are foreign keys, e.g. Section-Classroom
  - Are something else, e.g.
     Advisor
- This something else is called and Associative Entity.
- SQL requires and Associative Entity if
  - The relationship is many-to-many.
  - There are properties on the relationshi

## **Associative Entity**

- The ER model represents "associations/relationships" as
  - First class "things"
  - That are different from "entities."
- The SQL model does not have "relationships" or associations as first-class types. You have
  - Tables
  - Columns
  - Keys
  - Constraints
  - **–** ... ..
- You can implement some "relationships" using foreign keys. Others require something more complex – an associative entity.

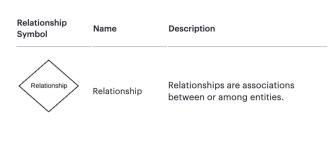

Associative entity

Associative entities relate the instances of several entity types. They also contain attributes specific to the relationship between those entity instances.

#### **ERD** relationship symbols

Within entity-relationship diagrams, relationships are used to document the interaction between two entities. Relationships are usually verbs such as assign, associate, or track and provide useful information that could not be discerned with just the entity types.

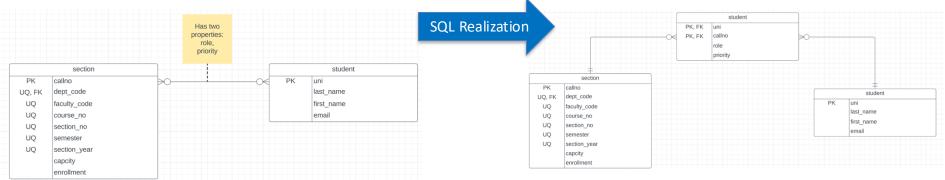

Weak Relationships are connections between a weak entity and its owner.

## **Associative Entity**

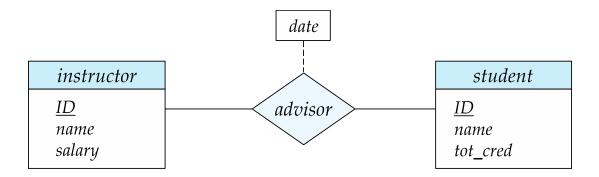

- "An associative entity is a term used in relational and entity—relationship theory. A relational database requires the implementation of a base relation (or base table) to resolve many-to-many relationships. A base relation representing this kind of entity is called, informally, an associative table." (<a href="https://en.wikipedia.org/wiki/Associative entity">https://en.wikipedia.org/wiki/Associative entity</a>)
- Consider Students Sections:
  - This is many-to-many. There is no way to implement in SQL. You see this in the Advises table in the sample database.
  - The "relationship/association" has properties that are not attributes of the connected entities.

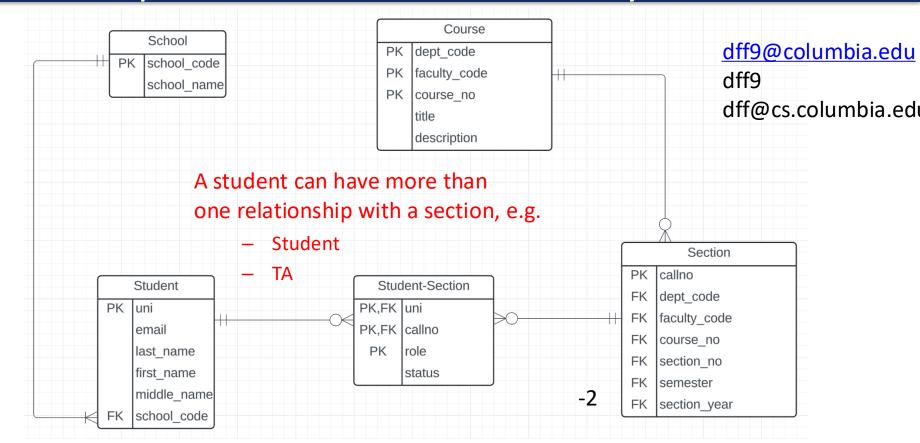

Switch to notebook diagram.

## **Relationship Sets with Attributes**

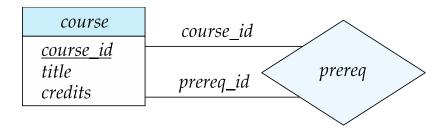

## An Example from Columbia University Model

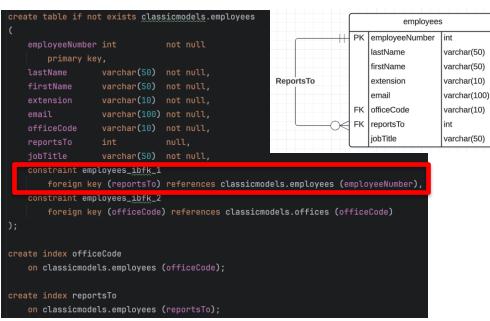

#### **Roles**

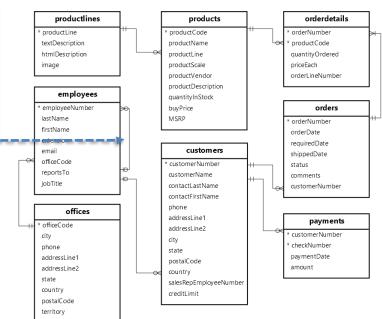

- Entity sets of a relationship need not be distinct
  - Each occurrence of an entity set plays a "role" in the relationship
- The labels "course\_id" and "prereq\_id" are called roles.

## Another Example – Classic Models

- Another simple but representative example we use is Classic Models
   (<a href="https://www.mysqltutorial.org/getting-started-with-mysql/mysql-sample-database/">https://www.mysqltutorial.org/getting-started-with-mysql/mysql-sample-database/</a>).
- You can see an example of a non-distinct entity sets.

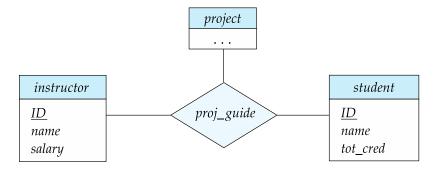

#### **Degree of a Relationship Set**

- Binary relationship
  - involve two entity sets (or degree two).
  - most relationship sets in a database system are binary.
- Relationships between more than two entity sets are rare. Most relationships are binary. (More on this later.)
  - Example: students work on research projects under the guidance of an instructor.
  - relationship proj\_guide is a ternary relationship between instructor, student, and project

#### **Non-binary Relationship Sets**

- Most relationship sets are binary
- There are occasions when it is more convenient to represent relationships as non-binary.
- E-R Diagram with a Ternary Relationship

#### **Mapping Cardinality Constraints**

- Express the number of entities to which another entity can be associated via a relationship set.
- Most useful in describing binary relationship sets.
- For a binary relationship set the mapping cardinality must be one of the following types:
  - One to one
  - One to many
  - Many to one
  - Many to many

Let's Examine and Do Some Examples

# Relational Model

Keys COLUMBIA | ENGINEERING
The Fu Foundation School of Engineering and Applied Science

© Donald F. Ferguson, 2024

27 | COMS W4111\_003\_2024\_3: Lecture 3: ER(2), Relational(2), SQL(2)

## **Keys**

- 1, Ferguson, COMS
- 2, Smith, EE
- 3, Duncan, MATH

- Let K ⊂ R
  - instructor(id, name, dept\_name) → R = {id, name, dept\_code}
  - {id, name}, {id}, {id, dept\_name}
- K is a superkey of R if values for K are sufficient to identify a unique tuple of each possible relation r(R)
  - Example: {ID} and {ID,name} are both superkeys of instructor.
- Superkey K is a candidate key if K is minimal Example: {ID} is a candidate key for Instructor
- One of the candidate keys is selected to be the primary key.
  - which one?
- Foreign key constraint: Value in one relation must appear in another
  - Referencing relation
  - Referenced relation
  - Example: dept\_name in instructor is a foreign key from instructor referencing department

## Notation

#### Classroom relation

building	room_number	capacity
Packard	101	500
Painter	100	125
Painter	514	10
Taylor	3128	70
Watson	100	30
Watson	120	50

#### classroom schema

It is customary to list the primary key attributes of a relation schema before the other attributes; for example, the *dept\_name* attribute of *department* is listed first, since it is the primary key. Primary key attributes are also underlined.

- The primary key is a composite key. Neither column is a key (unique) by itself.
- Keys are statements about all possible, valid tuples and not just the ones in the relation.
  - Capacity is unique in this specific data, but clearly not unique for all possible data.
  - In this domain, there cannot be two classrooms with the same building and room number.
- Relation schema:
  - Underline indicates a primary key column. There is no standard way to indicate other types of key.
  - We will use **bold** to indicate foreign keys.
  - You will sometimes see things like classroom(<u>building:string</u>, <u>room\_number:number</u>, capacity:number)

## **Observations**

#### Keys:

- Will be baffling. It takes time and experience to understand/appreciate.
- There are many, many types of keys with formal definitions.
- I explain the formality but focus on the concepts and applications.
- No one uses the formal, relational model. So, why do we study it?
  - Is very helpful when understanding concepts that we cover later in the course, especially query optimization and processing.
  - There are many realizations of the model and algebra, and understanding the foundation helps with understanding language/engine capabilities.
  - The model has helped with innovating new approaches, and you may innovate in data and query models in your future.

## A Note on Keys

- Relational model/algebra:
  - In the "pure" model, foreign keys reference primary keys.
  - This is not always the case in "real" databases and SQL.
  - There is no standard/common way to show foreign keys in relational schema. If I ask you to do
    it, you can pick a convention and add a note, e.g.

```
Student(ID, dept_code, name, tot_cred)
```

- When doing modeling for implementations, there are many kinds/styles of key:
  - Alternate UNI, email
  - Composite 202149 (COMS, W, 4111, 003, 003, 2024)
  - Natural (<u>COMS</u>, <u>W</u>, <u>4111</u>, "Introduction to Database", "The worst experience of your life.")
  - Surrogate (dff9, Ferguson, Donald, F., 012345, dff9@Columbia.edu)
  - Unique
  - **–** ... ...

# Relational Algebra (2) More Advanced Operators

#### **Relational Query Languages**

- Procedural versus non-procedural, or declarative
- "Pure" languages:
  - Relational algebra
  - Tuple relational calculus
  - Domain relational calculus
- The above 3 pure languages are equivalent in computing power
- We will concentrate in this chapter on relational algebra
  - Not turning-machine equivalent
  - Consists of 6 basic operations

#### **DFF Comments:**

- You will sometimes see other operator, e.g. ← Assignment.
- Relational algebra focuses on retrieve. You can sort of do Create, Update, Delete.
- The SQL Language, which we will see, extends relational algebra.

#### **Relational Algebra**

- A procedural language consisting of a set of operations that take one or two relations as input and produce a new relation as their result.
- Six basic operators
  - select: σ
  - project: ∏
  - union: ∪
  - set difference: –
  - Cartesian product: x
  - rename: ρ

#### **Join Operation**

The Cartesian-Product

instructor X teaches

associates every tuple of instructor with every tuple of teaches.

- Most of the resulting rows have information about instructors who did NOT teach a particular course.
- To get only those tuples of "instructor X teaches" that pertain to instructors and the courses that they taught, we write:

```
\sigma_{instructor.id = teaches.id} (instructor x teaches))
```

- We get only those tuples of "instructor X teaches" that pertain to instructors and the courses that they taught.
- The result of this expression, shown in the next slide

#### A fundamental definition:

- $\sigma_{\text{instructor,ID=teaches,ID}}$  (instructor × teaches) = instructor  $\bowtie$  teaches
- ⋈ is the JOIN operations.

## **JOIN Definition**

 $\sigma_{instructor,ID = teaches,ID}$  (instructor × teaches)

instructor ⋈ teaches

instructor.ID	instructor.name	instructor.dept_name	instructor.salary	teaches.ID	teaches.course_id	teaches.sec_id	teaches.semester	teaches.year
10101	'Srinivasan'	'Comp. Sci.'	65000	10101	'CS-101'	1	'Fall'	2009
10101	'Srinivasan'	'Comp. Sci.'	65000	10101	'CS-315'	1	'Spring'	2010
10101	'Srinivasan'	'Comp. Sci.'	65000	10101	'CS-347'	1	'Fall'	2009

45565	'Katz'	'Comp. Sci.'	75000	'CS-319'	1	'Spring'	2010
76766	'Crick'	'Biology'	72000	'BIO-101'	1	'Summer'	2009

 $\sigma_{instructor.ID=teaches.ID}$  (instructor × teaches)

instructor ⋈ teaches

instructor ⋈ <sub>instructor.ID>teaches.ID</sub> teaches

### Join Operation (Cont.)

- The join operation allows us to combine a select operation and a Cartesian-Product operation into a single operation.
- Consider relations r(R) and s(S)
- Let "theta" be a predicate on attributes in the schema R "union" S. The join operation  $r \bowtie_{\theta} s$  is defined as follows:

$$r \bowtie_{\theta} s = \sigma_{\theta} (r \times s)$$

Thus

$$\sigma_{instructor.id = teaches.id}$$
 (instructor x teaches))

Can equivalently be written as

*instructor* ⋈ *Instructor.id* = *teaches.id teaches.* 

### The Dreaded Relax Calculator

- Let's look at an online tool that you will use.
- RelaX (<a href="https://dbis-uibk.github.io/relax/calc/local/uibk/local/0">https://dbis-uibk.github.io/relax/calc/local/uibk/local/0</a>)
- The calculator:
  - Has an older version of the data from the recommended textbook.
     (https://dbis-uibk.github.io/relax/calc/gist/4f7866c17624ca9dfa85ed2482078be8/relax-silberschatz-english.txt/0)
  - You can also upload new data.
- Some queries:
  - σ dept\_name='Comp. Sci.' V dept\_name='History' (department)
  - π name, dept\_name (instructor)
  - π ID, name (σ dept\_name='Comp. Sci.' (instructor)

### Some Terms

- "A NATURAL JOIN is a JOIN operation that creates an implicit join clause for you based on the common columns in the two tables being joined.
   Common columns are columns that have the same name in both tables." (https://docs.oracle.com/javadb/10.8.3.0/ref/rrefsqljnaturaljoin.html)
- M → Natural Join in relational algebra.
- instructor  $\bowtie$  Instructor.id = teaches.id teaches is called a theta join.
- So, think about it ...
  - I showed you how to produce all possible pairs.
  - I showed you how to produce all naturally matching pairs.

### What are all those other Symbols? (Will Cover)

- τ order by
- γ group by
- ¬ negation
- ÷ set division
- ⋈ natural join, theta-join
- ⋈ left outer join
- ⋈ right outer join
- full outer join
- ⋈ right semi join
- ▷ anti-join

- Some of these are pretty obscure
  - Division
  - Anti-Join
  - Left semi-join
  - Right semi-join
- Most SQL engines do not support them.
  - You can implement them using combinations of JOIN, SELECT, WHERE, ......
  - But, I cannot every remember using them in applications I have developed.
- Outer JOIN is very useful, but less common. We will cover.
- There are also some "patterns" or "terms"
  - Equijoin
  - Non-equi join
  - Natural join
  - Theta join
  - ... ...
- I may ask you to define these terms on some exams because they may be common internships/job interview questions.

# Let's Do Some Examples

SQL

# Data Definition Language

### **Data Definition Language**

The SQL data-definition language (DDL) allows the specification of information about relations, including:

- The schema for each relation.
- The type of values associated with each attribute.
- The Integrity constraints
- The set of indices to be maintained for each relation.
- Security and authorization information for each relation.
- The physical storage structure of each relation on disk.

### **Domain Types in SQL**

- char(n). Fixed length character string, with user-specified length n.
- varchar(n). Variable length character strings, with user-specified maximum length n.
- int. Integer (a finite subset of the integers that is machine-dependent).
- smallint. Small integer (a machine-dependent subset of the integer domain type).
- numeric(p,d). Fixed point number, with user-specified precision of p digits, with d digits to the right of decimal point. (ex., numeric(3,1), allows 44.5 to be stores exactly, but not 444.5 or 0.32)
- **real**, **double precision**. Floating point and double-precision floating point numbers, with machine-dependent precision.
- **float(n).** Floating point number, with user-specified precision of at least *n* digits.
- More are covered in Chapter 4.

## MySQL Data Types (Subset)

### **MySQL DATA TYPES**

DATE TYPE	SPEC	DATA TYPE	SPEC
CHAR	String (0 - 255)	INT	Integer (-2147483648 to 214748- 3647)
VARCHAR	String (0 - 255)	BIGINT	Integer (-9223372036854775808 to 9223372036854775807)
TINYTEXT	String (0 - 255)	FLOAT	Decimal (precise to 23 digits)
TEXT	String (0 - 65535)	DOUBLE	Decimal (24 to 53 digits)
BLOB	String (0 - 65535)	DECIMAL	"DOUBLE" stored as string
MEDIUMTEXT	String (0 - 16777215)	DATE	YYYY-MM-DD
MEDIUMBLOB	String (0 - 16777215)	DATETIME	YYYY-MM-DDHH:MM:SS
LONGTEXT	String (0 - 4294967295)	TIMESTAMP	YYYYMMDDHHMMSS
LONGBLOB	String (0 - 4294967295)	TIME	HH:MM:SS
TINYINT	Integer (-128 to 127)	ENUM	One of preset options
SMALLINT	Integer (-32768 to 32767)	SET	Selection of preset options
MEDIUMINT	Integer (-8388608 to 8388607)	BOOLEAN	TINYINT(1)

Note: Scroll through https://www.mysqldatatypes.com/

#### **Create Table Construct**

An SQL relation is defined using the create table command:

#### create table r

```
(A_1 D_1, A_2 D_2, ..., A_n D_n,
(integrity-constraint<sub>1</sub>),
...,
(integrity-constraint<sub>k</sub>))
```

- r is the name of the relation
- each A<sub>i</sub> is an attribute name in the schema of relation r
- D<sub>i</sub> is the data type of values in the domain of attribute A<sub>i</sub>
- Example:

```
create table instructor (

ID char(5),

name varchar(20),

dept_name varchar(20),

salary numeric(8,2))
```

### **Integrity Constraints in Create Table**

- Types of integrity constraints
  - primary key  $(A_1, ..., A_n)$
  - foreign key (A<sub>m</sub>, ..., A<sub>n</sub>) references r
  - not null
- SQL prevents any update to the database that violates an integrity constraint.
- Example:

### **And a Few More Relation Definitions**

create table student ( ID varchar(5), varchar(20) not null, name dept\_name varchar(20), tot cred numeric(3,0),primary key (ID), **foreign key** (dept\_name) **references** department); create table takes ( ID varchar(5), course id varchar(8), sec\_id varchar(8), semester varchar(6), numeric(4,0),vear varchar(2), arade primary key (ID, course\_id, sec\_id, semester, year) , foreign key (ID) references student, foreign key (course\_id, sec\_id, semester, year) references section);

### And more still

create table course (

```
course_id varchar(8),
title varchar(50),
dept_name varchar(20),
credits numeric(2,0),
primary key (course_id),
foreign key (dept_name) references department);
```

### **Integrity Constraints**

- Integrity constraints guard against accidental damage to the database, by ensuring that authorized changes to the database do not result in a loss of data consistency.
  - A checking account must have a balance greater than \$10,000.00
  - A salary of a bank employee must be at least \$4.00 an hour
  - A customer must have a (non-null) phone number

### **Constraints on a Single Relation**

- not null
- primary key
- unique
- **check** (P), where P is a predicate

### **Not Null Constraints**

- not null
  - Declare name and budget to be not null name varchar(20) not null budget numeric(12,2) not null

### **Unique Constraints**

- unique  $(A_1, A_2, ..., A_m)$ 
  - The unique specification states that the attributes  $A_1, A_2, ..., A_m$  form a candidate key.
  - Candidate keys are permitted to be null (in contrast to primary keys).

### The check clause

- The check (P) clause specifies a predicate P that must be satisfied by every tuple in a relation.
- Example: ensure that semester is one of fall, winter, spring or summer

```
create table section
  (course_id varchar (8),
   sec_id varchar (8),
   semester varchar (6),
   year numeric (4,0),
   building varchar (15),
   room_number varchar (7),
   time slot id varchar (4),
   primary key (course_id, sec_id, semester, year),
   check (semester in ('Fall', 'Winter', 'Spring', 'Summer')))
```

### **Referential Integrity**

- Ensures that a value that appears in one relation for a given set of attributes also appears for a certain set of attributes in another relation.
  - Example: If "Biology" is a department name appearing in one of the tuples in the *instructor* relation, then there exists a tuple in the *department* relation for "Biology".
- Let A be a set of attributes. Let R and S be two relations that contain attributes A and where A is the primary key of S. A is said to be a foreign key of R if for any values of A appearing in R these values also appear in S.

### **Referential Integrity (Cont.)**

 Foreign keys can be specified as part of the SQL create table statement

**foreign key** (dept\_name) **references** department

- By default, a foreign key references the primary-key attributes of the referenced table.
- SQL allows a list of attributes of the referenced relation to be specified explicitly.

**foreign key** (dept\_name) **references** department (dept\_name)

### **Cascading Actions in Referential Integrity**

- When a referential-integrity constraint is violated, the normal procedure is to reject the action that caused the violation.
- An alternative, in case of delete or update is to cascade

- Instead of cascade we can use :
  - set null,
  - set default

### **Integrity Constraint Violation During Transactions**

Consider:

- How to insert a tuple without causing constraint violation?
  - Insert father and mother of a person before inserting person
  - OR, set father and mother to null initially, update after inserting all persons (not possible if father and mother attributes declared to be not null)
  - OR defer constraint checking

# Let's Do Some Examples

- Generated values for section ID.
- Enumerations for faculty code and section.
- Check constrains.
- ... ...

# JOIN Operator

### **Joined Relations**

- Join operations take two relations and return as a result another relation.
- A join operation is a Cartesian product which requires that tuples in the two relations match (under some condition). It also specifies the attributes that are present in the result of the join
- The join operations are typically used as subquery expressions in the from clause
- Three types of joins:
  - Natural join
  - Inner join
  - Outer join

#### Notes:

- You will also hear terms like equi-join, non-equi-join, theta join, semi-join, ... ...
- I ask for definitions on exams, but you can just look them up.

### **Natural Join in SQL**

- Natural join matches tuples with the same values for all common attributes, and retains only one copy of each common column.
- List the names of instructors along with the course ID of the courses that they taught
  - select name, course\_id
     from students, takes,
     where student.ID = takes.ID;
- Same query in SQL with "natural join" construct
  - select name, course\_id
     from student natural join takes;

### **Natural Join in SQL (Cont.)**

• The from clause can have multiple relations combined using natural join:

```
select A_1, A_2, ... A_n
from r_1 natural join r_2 natural join .. natural join r_n
where P;
```

### **Student Relation**

ID	name	dept_name	tot_cred
00128	Zhang	Comp. Sci.	102
12345	Shankar	Comp. Sci.	32
19991	Brandt	History	80
23121	Chavez	Finance	110
44553	Peltier	Physics	56
45678	Levy	Physics	46
54321	Williams	Comp. Sci.	54
55739	Sanchez	Music	38
70557	Snow	Physics	0
76543	Brown	Comp. Sci.	58
76653	Aoi	Elec. Eng.	60
98765	Bourikas	Elec. Eng.	98
98988	Tanaka	Biology	120

### **Takes Relation**

ID	course_id	sec_id	semester	year	grade

### **Dangerous in Natural Join**

- Beware of unrelated attributes with same name which get equated incorrectly
- Example -- List the names of students instructors along with the titles of courses that they have taken
  - Correct version

**select** name, title **from** student **natural join** takes, course **where** takes.course id = course.course id;

Incorrect version

select name, title from student natural join takes natural join course;

- This query omits all (student name, course title) pairs where the student takes a course in a department other than the student's own department.
- The correct version (above), correctly outputs such pairs.

### **Natural Join with Using Clause**

- To avoid the danger of equating attributes erroneously, we can use the "using" construct that allows us to specify exactly which columns should be equated.
- Query example

select name, title
from (student natural join takes) join course using (course\_id)

#### **Join Condition**

- The on condition allows a general predicate over the relations being joined
- This predicate is written like a where clause predicate except for the use of the keyword on
- Query example

```
select *
from student join takes on student_ID = takes_ID
```

- The on condition above specifies that a tuple from student matches a tuple from takes if their ID values are equal.
- Equivalent to:

```
select *
from student , takes
where student_ID = takes_ID
```

### **Join Condition (Cont.)**

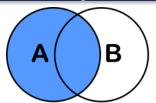

- The on condition allows a general predicate over the relations being joined.
- This predicate is written like a where clause predicate except for the use of the keyword on.
- Query example

```
select *
from student join takes on student_ID = takes_ID
```

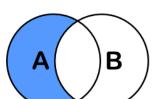

- The on condition above specifies that a tuple from student matches a tuple from takes if their ID values are equal.
- Equivalent to:

```
select *
from student , takes
where student_ID = takes_ID
```

### One Way to Think About Joins

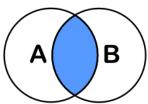

SELECT <auswahl> FROM tabelleA A LEFT JOIN tabelleB B ON A.key = B.key

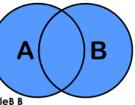

SELECT <auswahl> FROM tabelleA A LEFT JOIN tabelleB B ON A.key = B.key WHERE B.key IS NULL

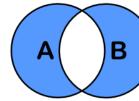

SELECT <auswahl>
FROM tabelleA A
FULL OUTER JOIN tabelleB B
ON A.key = B.key

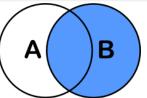

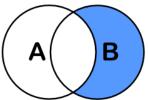

SELECT <auswahl> FROM tabelleA A INNER JOIN tabelleB B ON A.key = B.key

SELECT <auswahl> FROM tabelleA A RIGHT JOIN tabelleB B ON A.key = B.key

SELECT <auswahl>
FROM tabelleA A
RIGHT JOIN tabelleB B
ON A.key = B.key
WHERE A.key IS NULL

SELECT <auswahl>
FROM tabelleA A
FULL OUTER JOIN tabelleB B
ON A.key = B.key
WHERE A.key IS NULL
OR B.key IS NULL

## **Database Modification**

### **Modification of the Database**

- Deletion of tuples from a given relation.
- Insertion of new tuples into a given relation
- Updating of values in some tuples in a given relation

### **Deletion**

Delete all instructors

delete from instructor

- Delete all instructors from the Finance department delete from instructor where dept\_name= 'Finance';
- Delete all tuples in the instructor relation for those instructors associated with a department located in the Watson building.

### **Deletion (Cont.)**

 Delete all instructors whose salary is less than the average salary of instructors

- Problem: as we delete tuples from instructor, the average salary changes
- Solution used in SQL:
  - 1. First, compute **avg** (salary) and find all tuples to delete
  - 2. Next, delete all tuples found above (without recomputing **avg** or retesting the tuples)

### Insertion

Add a new tuple to course

```
insert into course
   values ('CS-437', 'Database Systems', 'Comp. Sci.', 4);
```

or equivalently

```
insert into course (course_id, title, dept_name, credits)
   values ('CS-437', 'Database Systems', 'Comp. Sci.', 4);
```

Add a new tuple to student with tot\_creds set to null

```
insert into student
  values ('3003', 'Green', 'Finance', null);
```

### **Insertion (Cont.)**

 Make each student in the Music department who has earned more than 144 credit hours an instructor in the Music department with a salary of \$18,000.

```
insert into instructor
    select ID, name, dept_name, 18000
from student
    where dept_name = Music' and total_cred > 144;
```

The **select from where** statement is evaluated fully before any of its results are inserted into the relation.

Otherwise queries like

insert into table1 select \* from table1

would cause problem

### **Updates**

Give a 5% salary raise to all instructors

```
update instructor
set salary = salary * 1.05
```

Give a 5% salary raise to those instructors who earn less than 70000 update instructor

set salary = salary \* 1.05

where salary < 70000;

Give a 5% salary raise to instructors whose salary is less than average

### **Updates (Cont.)**

- Increase salaries of instructors whose salary is over \$100,000 by 3%, and all others by a 5%
  - Write two update statements:

```
update instructor
   set salary = salary * 1.03
   where salary > 100000;
update instructor
   set salary = salary * 1.05
   where salary <= 100000;</pre>
```

- The order is important
- Can be done better using the case statement (next slide)

# Wrap Up
